

RedFish – Production, Inventory, and Dispatch Management

Problem

The fish-breeding manages information related to production, inventory, and dispatches in a scattered manner, which can lead to information loss, errors, and difficulties in accessing data in real time.

Objective

Develop a distributed system that centralizes and manages the fish-breeding information, facilitating the control of production, inventory, and dispatches.

Users

- Production
- Inventory
- Dispatch

Main Features

- Feeding control.
- Inventory management.
- Order registration.
- Dispatch and vehicle management.

Architecture

The system will use a client-server architecture, where different users can access the system through a network and consult or update the information stored on a central server.

Expected Result

Have a platform that improves the control of the fish farm's operations, reduces errors, and facilitates access to information.
